Abstract
The development of biomedical electronics, biosynthesis of ZnS nanoparticles (NPs) much attracted researchers, due to an eco-friendly and cost effective routes for synthesis ZnS nanoparticles. In this present work ZnS NPs was synthesized by using acalypha indica and curcuma longa plant extract using chemical co-precipitation method. The structural, morphological, element composition of biosynthesis ZnS NPs was characterized by XRD, SEM and EDAX respectively. Optical and photoluminescence (PL) properties was evaluated by UV Visible spectroscopy. The formation of inhibition zone diameter against human pathogenic microorganisms was screened by in vitro disc diffusion method. From this investigation formation of inhibition zones clearly shows biosynthesized ZnS NPs have high antimicrobial activity against tested organisms, especially curcuma longa plant extract mediated ZnS NPs was formed maximum inhibition against all the tested microorganism.

Introduction
In the last two decades, fabrication of inorganic semiconductor materials widely attracted researchers because of their excellent chemical and physical properties. Among all II-VI group semiconductors, ZnS having cubic and hexagonal crystal structure with large band gap (~3.63 eV) and high refractive index in the visible range.1-4 The various synthesized method has been used to fabricate ZnS such as thermal decomposition, sol-gel technique, microemulsion method hydrothermal method, CVD, CBD, Microwave assisted, sonochemical method, soft chemistry method, etc.5-12 The bio-fabricated nanoparticles were used various applications like solar cells, field emitters, ultraviolet light-injection lasers, emitting diodes, electroluminescent devices, infrared windows, spintronics, flat-panel displays, optoelectronics, sensors, photocatalysis and antimicrobial activity.13-22 acalypha indica and and curcuma longa is good medicinal plant and widely

used novel drug medicine, green pharmacy due to the antimicrobial activity\textsuperscript{23}. In the recent time, biosynthesis of ZnS NPs using different biological extracts were reported.\textsuperscript{24-25} Biosynthesized ZnS NPs from various plant extracts has been already reported by our earliest reports. Biosynthesized ZnS NPs exhibits rapid generation of electron-hole pairs by photo-excitation and the highly negative reduction potentials of excited electrons have been generated high electron-hole pair when treated under UV visible light, and it increases antimicrobial properties.\textsuperscript{26-27} In this present investigation we reported structural optical and antimicrobial activity of ZnS NPs using \textit{acalypha indica} and \textit{curcuma longa} plants extract.

**Experimental Procedure**

**Plant Extracts Preparation**

\textit{acalypha indica} and \textit{curcuma longa} plants are collected from Herbal garden Coimbatore. For remove soils and dusts, the collected plants are washed in deionized water followed by under running tab water. Then it’s treated shadow drying for 10 days at room temperature. The dried plant materials are crushed to coarsely powdered by grinder and 250 g of plant powder extracted by 250 ml of methanol solvent using soxhlet apparatus\textsuperscript{28} the prepared plant extracts has been used for further investigation.

**Biofabrication of ZnS**

The bio-fabrication of ZnS nanoparticles were prepared by using 20 ml plant extract and 1:1 molar ratio of ZnSO\textsubscript{4}.7H\textsubscript{2}O (zinc sulfate) and NH\textsubscript{2}CSNH\textsubscript{2} (thiourea) as a source materials. The both ZnSO\textsubscript{4}.7H\textsubscript{2}O and NH\textsubscript{2}CSNH\textsubscript{2} were dissolved in 50 ml of deionized water in two different beakers and the mixtures was stirred 30 min by using magnetic stirrer. While continuous stirring, NH\textsubscript{2}CSNH\textsubscript{2} and 20 ml of plant extract solution were added drop by drop into ZnSO\textsubscript{4}.7H\textsubscript{2}O solution and the mixture was kept 60 min stirring. The resultant nono-colloidal was formed and it was centrifuged at 2000 rpm for 20 min further it’s heated in air furnace at 100 °C for 12 hours for obtain fine nanoparticles. Pure ZnS nanoparticles were prepared by same

experimental procedure presented above but plant extracts are could not be used for synthesis ZnS, for comparative evaluation, prepared ZnS nanoparticles was abbreviated following namely, pure ZnS as ZnS, *acalypha indica* and *curcuma longa* plant extract as A:ZnS and C:ZnS respectively. Schematic representation for the preparation and antimicrobial activity of Biosynthesized ZnS showed in figure 1.

**Characterization Method**

The Biosynthesized ZnS samples were characterized by XRD technique in the 2θ range of 10°-80° with 0.1° step size using Cu-Kα radiation ($\lambda = 1.54056$ Å) to determine crystal structure. Surface morphology and element compound presence in the ZnS was found by scanning electron microscopy with element analyzer (Hitachi S-4500). The optical absorbance and photoluminescence properties were found by Perkin Elmer UV/VIS/NIR and JASCO FT/1 IR-6600 instrument respectively.

**Susceptibility Test Preparation**

Antimicrobial activity of prepared ZnS nanoparticles has been determined by the diameter formation of inhibition zone, *In vitro* disc diffusion method has been used to investigate antimicrobial activity of human pathogenic microorganism's i.e: *B.substils, S.aures, E.coli, P.aerugoinosa, C.albicans* and *A.niger*. Microorganisms were maintained 4 °C on the slopes nutrient ager, MHA plates and the stock cultures were incubated for 24 hours at 37 °C and 25 °C respectively. Before transfer culture on the MHA plates, 15 ml of molten media pouring into MHA plates and solidify for 5 min. The minimum amount of stock culture (0.1%) were swapped on the MHA plates surface and 6 mm of sterile disc which have 60 µl concentration were placed on the MHA plate surface. The prepared ZnS samples were loaded on the sterile disc surface and allowed 5 min to diffuse samples into disc, and the loaded MHA plates are kept 24 hours in incubation at 37 °C, finally during the incubation inhibition zone was formed around the disc it has been calculated by transparent millimeter ruler.

**Result and Discussion**

**Structural analysis**

XRD pattern of the prepared ZnS, A:ZnS and C:ZnS samples shown in Fig. 2. All the prepared samples
exhibits three diffraction peaks well matched with zinc blended cubic structure. From this XRD results shows any other impurity peaks are not detected and its conformed well formation of ZnS NPs. Figure 2 shows the XRD pattern of prepared samples diffraction peaks indicates the presence of prominent peaks \(2\theta\) at 28.9°, 48.1° and 57.7° corresponding to the miller indices planes to (111), (220) and (311) reflection of ZnS cubic structure which well matched with JCPDS card no. 80-0020. The XRD pattern of A:ZnS and C:ZnS NPs shows high intensity diffraction peak at (111) plane so it was the evidence bioactive compound of plant extract helps to improve the crystal growth of ZnS nanoparticles. Table 1 shows the calculated average crystalline size of ZnS nanoparticles using Debye Scherer formula

\[
D = \frac{0.9 \lambda}{\beta \cos \theta}
\]

Where, D is the mean crystallite size, \(\beta\) is the full width at half maximum of the diffraction line, \(\theta\) is diffraction angle, \(\lambda\) is the wavelength of X ray radiation and 0.9 is the constant shape factor.

**Morphological and Element Composition Analysis**

The morphological and element composition of prepared ZnS NPs was investigated by using SEM and EDAX. The SEM images of synthesized ZnS
NPs are having narrow particle size with spherical shape as shown in Fig. 3(a-c). Surface morphology of the ZnS nanoparticles was varied by the plant extract; from this SEM image revealed bio-fabricated ZnS having uniform distribution of plant extract and improve the crystalline structure of ZnS NPs as shown in Fig. 3 (b-c). The C: ZnS nanoparticle is smaller than ZnS and A: ZnS and diameter of the prepared samples was varied depends on the plant extracts. Fig. 4(a-c) shows the EDAX image of pure and biological synthesized ZnS NPs, from this result Zn and S elements were presence in pure ZnS NPs and the Zn (63.59%) composition element was found higher than S (36.41%) element in ZnS NPs and no other impurities observed in the spectrum it was clearly shown in Fig. 4 (a). In the EDAX image, A:ZnS NPs composition was confirmed with presence of Zn, S, Carbon, Oxygen elements in the atomic ratio of 41.23%, 31.94% 16.21% and 10.62% respectively from this spectrum biomolecules of plant extract was influence to composite the carbon and oxygen element as shown in Fig. 4 (b). The Zn, S, Carbon, Oxygen elements also presence in C:ZnS in the atomic ratio of 46.24%, 31.93% 15.20% and 06.63% respectively it is shown in Fig. 4(c).

![Fig. 6. Photoluminescence spectrum of (a) ZnS, (b) A:ZnS, (c) C:ZnS](image)

![Fig. 7: Show the Zoi for (a) ZnS, (b) A:ZnS, (c) C:ZnS NPs against different microorganisms](image)
Optical Absorption and Photoluminescence Properties

Figure 5 shows the UV-Visible absorbance spectroscopy of prepared samples and all the samples exhibits maximum optical absorbance of 75% was observed. The high absorption peaks at 318 nm, 321 nm and 324 nm for ZnS, A:ZnS and C:ZnS respectively. The bio fabricated ZnS having maximum absorption were found red shifted for ZnS. Tauc’s plot has been used to calculate band gap energy

\[ \alpha \nu = A(\nu^2 - E_g) \]

...(2)

Its relation between absorption coefficient and photon energy and optical absorption coefficient is \( \alpha \), \( \nu \) is planks constant, \( A \) is constant, optical band gap energy is \( E_g \) and photon energy is \( \nu \). The calculated band gap value of ZnS, A:ZnS and C:ZnS is 3.89 eV, 3.86 eV and 3.82 eV respectively. From the result band gap was decreased 3.89 (eV) to 3.82(eV) due to surface roughness of biological synthesized ZnS also the band gap was found higher than bulk ZnS which suitable for cubic structure.

The band gap energy was increased efficiently due to minimum transition of electron from valence band to conductance band. The photoluminescence (PL) spectrum of all the prepared ZnS NPs samples excitation wavelength is 320 nm. The broad peak appearance at 408 nm and 428 nm due to the presence of sulphur and zinc vacancies of all the prepared ZnS samples because PL spectra large intensity is depends on the crystalline size and large surface volume ratio of NPs. The Pure ZnS NPs depicts a strong intensity than all other plant extract capped ZnS NPs. C:ZnS NPs intensity was increase due to higher surface volume ratio and smaller particle size of A:ZnS NPs it is shown in Fig. 6.

Antimicrobial Properties Analysis

Antimicrobial activity of prepared ZnS samples has been determined by the formation of inhibition zone, *In vitro* disc diffusion method has been used to investigate antimicrobial activity of human pathogenic microorganism’s i.e: *B.subtilis*, *S.aures*, *E.coli*, *Paeruginosa*, *C.albicans* and *A.niger*. Table 2 and figure 7 and 8 shows the zone of inhibition and bar diagram of inhibition zone against human pathogens. The maximum inhibition zone was

<table>
<thead>
<tr>
<th>Samples / Concentrations (µl)</th>

</table>
observed against *E. coli* and *C. albicans* followed by *S. aureus*, *P. aeruginosa*, *A. niger* and *B. subtilis* of 17 mm followed by 16 mm, 14 mm, 14 mm, 13 mm at 60 µl of concentration respectively, its clearly indicate when concentration is increased the inhibition zone also increased due high surface absorption of bacteria cell.

For A:ZnS NPs was found highest inhibition zone against *P. aeruginosa* followed by *E. coli*, *C. albicans*, *S. aureus*, *B. subtilis* and *A. niger* of 22 mm, 20 mm, 20 mm, 14 mm, 18 mm and 15 mm at 60 µl of concentration respectively, *P. aeruginosa* has higher inhibition zone at starting concentration when compared to other microorganisms due to presence of bioactive compound of plant extract such as phenolic, saponin, terponoids, etc. The maximum inhibition zone of C:ZnS NPs was found against *C. albicans* followed by *E. coli*, *S. aureus*, *B. subtilis*, *P. aeruginosa* and *A. niger* of 29 mm, 25 mm, 23 mm, 22 mm, 22 mm and 20 mm at 60 µl of concentration respectively, from this investigation since at starting concentration *C. albicans* lead to form high inhibition zone.

From this investigation we found maximum inhibition zone against gram negative bacteria followed by gram positive and fungus culture for bio-fabricated ZnS, this may happen due to presence of bioactive compounds like saponin, phenols, terponoids, proteins and carbohydrates which may help to formation of large surface area nanoparticle penetrate into bacteria cell wall and causes cell death.\textsuperscript{34-35}

**Conclusion**

In summary, we reported the bio fabricated ZnS NPs were prepared by using plant extracts of *acalypha indica* and *curcuma longa*. The cubic crystalline structure was confirmed for all the ZnS NPs and the average particle was found to be 15-18 nm. The smaller crystalline size was found to bio-fabricated ZnS nanoparticles compare to ZnS NPs and morphology was found the spherical shape like structure. The band gap energy was calculated from 3.89 eV to 3.82 eV and the purity of different element composition of plant extract was reveals from EDAX. The antimicrobial activity was investigated against different human pathogens, maximum zone of inhibition was formed for plant extract mediated ZnS when compared pure ZnS nanoparticles due to influence of smaller crystal size and presence of bimolecular from plant extracts.
