ABSTRACT

H₂PtCl₆ was used for the preparation of Pt/Al₂O₃ by thermal treatment at 380°C then, reduction by hydrogen. Dispersion of Pt/Al₂O₃ was much higher when the pretreatment of H₂PtCl₆ was done in oxygen atmosphere at 380°C then in helium atmosphere.

The intermediates formed through the investigated thermal pretreatment processes were PtCl₄ and PtCl₂ at 260°C and 380°C respectively when helium was the atmosphere of pretreatment, while Pt(OH)Cl₃, PtOCI₂ and probably PtO2 were obtained at the above temperature when oxygen was the atmosphere of the pretreatment.

Keywords: Dispersion, Pt/Al₂O₃, chloroplatinic acid.

INTRODUCTION

An extensive study to the preparation of Pt/Al₂O₃ catalyst was formerly investigated due to its vast usage in the hydrogenation processes. Dispersion of the catalyst is of importance to catalyst efficiency. Dispersion of a catalyst is affected by many factors such as the method of pretreatment of the catalyst, namely the method of drying to remove water in the incipient wetness technique, the temperature range at which thermal treatment was done, the atmosphere of the reactor and the type of the impregnated precursor. It was reported that H₂PtCl₆ undergoes ligand exchange with OH at different acidity and temperature lower than 150°C leading to the formation of a series of hydrolyzed species of H₂PtCl₆.

In this study the Pt/Al₂O₃, was obtained by two methods of pretreatment. It is expected that the dispersion will differ according to the intermediates involved in each method. The methods of pretreatment are investigated here in order to find the pretreatment which gives the highest dispersed catalyst. Hydrogen chemisorption was used to estimate dispersion by the pulse dynamic method. Thermal gravimetric analysis was used for the investigation of the intermediates involved in the two different methods used for the catalyst preparation before reduction with hydrogen to get Pt/Al₂O₃.

EXPERIMENTAL

Chemicals: H₂PtCl₆ (99% purity, Aldrich)
Al₂O₃ (Surface Area 150 m²/g, high purity, Merck).
Apparatus: Thermal Gravimetric
Analyser (TGA) (Rheometric scientific STA 1500) and G.C 3400 (Varian).

Catalyst preparation: \( \text{H}_2\text{PtCl}_6\text{XH}_2\text{O}/\text{Al}_2\text{O}_3 \) was prepared by the incipient wetness technique. The appropriate weight of \( \text{H}_2\text{PtCl}_6\text{XH}_2\text{O} \) required to prepare a catalyst having a nominal weight loading of 5\% Pt was dissolved in an amount of deionized water. The solution was added to the \( \text{Al}_2\text{O}_3 \) support in a drop wise manner to give a thin slurry. The resulting slurry was dried in vacuum for 24 h at 25°C.

Pretreatment Schedules:

Method 1: A portion (0.250 g) of the dried catalyst was heated in flowing \( \text{O}_2 \) in the reactor to 380°C (the assigned reduction temperature) for 60 min. followed by outgassing with He for 10 min. then reduced by flowing \( \text{H}_2 \) for 2 h. outgassed with He for 1 h and then cooled to room temperature in flowing helium.

Method 2: Another portion of the dried catalyst was heated in flowing \( \text{He} \) (instead of \( \text{O}_2 \) in method 1) in the reactor to 380°C; the following steps were as in method 1.

Chemisorption measurements: Dispersion for each catalyst portion was measured using the pulse dynamic method for the pretreated sample in the glass micro reactor (6mm id silica, volume 4.4 mL). The chemisorption was performed by pulsing \( \text{H}_2 \) in to the He carrier gas. The \( \text{H}_2 \) was detected by a thermal conductivity detector of the G.C connected to a Varian integrator model 4290 Fig.1.

Thermal gravimetric analysis: 0.25 g of hydrated chloroplatinic acid was introduced into the furnace at room temperature A flow of 50 ml/min. of \( \text{He} \) or \( \text{O}_2 \) gas was used through a heating speed of 5°C/min. Mass loss graph was obtained for runs of \( \text{O}_2 \) and \( \text{He} \) at different temperature, Figures 2 and 3.

RESULTS AND DISCUSSION

The dispersion values obtained are in average 92% for method 1 and 52% for method 2 (Table 1), on the assumption of 1:1 for H : Pt stoichiometry. The difference in dispersion for the two methods cannot be attributed to the readiness of the reduction of the metal chloride (PtCl₂, PtCl₄) over the metal oxide, since it known that the chlorides of group VIII metals are easier to be reduced than their oxides. Therefore, the difference in the dispersion must be attributed to the type and strength of adsorption and the mobility of the metal precursor surface species formed before complete reduction to the Pt metal. The calcined Pt-precursor species is thought to

Fig. 2: Thermal gravimetric graph of H₂PtCl₆·XH₂O, in Oxygen atmosphere
be Pt(OH)Cl₃, PtOCl₂ and PtO₂, depending on the calcination temperature in the heating process of H₂PtCl₆ for the range 25-380°C. These species were found to be more mobile than those of metal chloride surface species formed in the He atmosphere through the heating process for the same temperature range. The change in mobility causes more rich surface of Pt species when the oxychloroplatinurj intermediates are formed. The thermal gravimetric analysis (TGA) of the chloroplatinic acid (H₂PtCl₆) in He and O₂ atmospheres was carried out to realize that the above species are formed through the two methods of the catalyst pretreatment that led after hydrogenation to Pt/AI₂O₃, figures 2 and 3.

According to the results of TGA, recorded in Table 2 and 3, the decompositions in He atmosphere are as follows:

\[
\begin{align*}
\text{H}_2\text{PtCl}_6 & \rightarrow \text{PtCl}_4 + 2\text{HCl} \\
\text{PtCl}_4 & \rightarrow \text{PtCl}_2 + \text{Cl}_2
\end{align*}
\]

Hence, it is concluded that PtCl and PtCl₂ are the intermediates formed in method 2. Also the percentage of the predicted products in O₂ shown in Table 2, led to the deduction of following:

\[
\begin{align*}
2\text{H}_2\text{PtCl}_6 + \frac{3}{2}\text{O}_2 & \rightarrow 2\text{Pt(OH)Cl}_3 + \text{H}_2\text{O} + 3\text{Cl}_2 & 137-296 \degree\text{C} \\
2\text{Pt(OH)Cl}_3 + \frac{1}{2}\text{O}_2 & \rightarrow 2\text{PtOCl}_2 + \text{H}_2\text{O} + \text{Cl}_2 & 296-380 \degree\text{C}
\end{align*}
\]

From these equations it is

</table>

The relative masses of the products at different temperature were taken from the TGA record listed in Fig.2 and 3.

Concluded that Pt(OH)Cl₂, PtOCl₂ and PtO₂ are the intermediates formed in method 1.

Recently, the results of temperature programmed reduction (TPR) and EXAFS studies by Choi et al., had proved that catalysts prepared from Pt(II) precursors were less reduced than those prepared from Pt(IV). Therefore, the low values of dispersion obtained in this study are due to the strong adsorption (low mobility) and the low reduction ability of the metal precursor surface species formed through the pretreatment of method 2. However, the high values of dispersion obtained in method 1 could be attributed to the formation of Pt(IV) chloroxynated species which are more mobile than the PtCl₂ species.

Heating 380 °C in method 2 will produce PtCl₂ which is known from above to be hardly reduced than PtCl₄. In method

The large difference between the theoretical and experimental is due to the formation of PtO₂ from PtOCl₂ at the temperature range 296-380°.
1. PtOCl₂ and PtO₂ are formed which are pretreatments used in this study the easily reduced and more mobile. In the two methods of the following might be occurring:

**Method 1:**

\[ \text{H}_2\text{PtCl}_6 \text{(hydrous)} \xrightarrow{\text{O}_2/25-137 \degree\text{C}} \text{H}_2\text{PtCl}_6 \text{(anhydrous)} \]

\[ \text{PtOCl}_2 + \text{PtO}_2 \xrightarrow{\text{O}_2/296-380 \degree\text{C}} \text{Pt(OI)Cl}_2 \]

\[ \text{Pt} \xrightarrow{\text{H}_2\text{T} > 380 \degree\text{C}} \text{PtOCl}_2 \]

**Method 2:**

\[ \text{H}_2\text{PtCl}_6 \text{(hydrous)} \xrightarrow{\text{He/25-195 \degree\text{C}}} \text{He} \text{PtCl}_6 \text{(anhydrous)} \]

\[ \text{He/195-290 \degree\text{C}} \]

\[ \text{Pt} \xrightarrow{\text{H}_2\text{T} > 380 \degree\text{C}} \text{PtCl}_2 \]  

\[ \text{PtCl}_2 \xrightarrow{260-370 \degree\text{C}} \text{He} \]
